Explanation

Claims in access tokens
 JWTs (JSON Web Tokens) are split into three pieces:
 * Header - Provides information about how to validate the token including information about the type of token and how it was signed.
 * Payload - Contains all of the important data about the user or app that is attempting to call your service.
 * Signature - Is the raw material used to validate the token.
 Your client can get an access token from either the v1.0 endpoint or the v2.0 endpoint using a variety of protocols.
 Scenario: User authentication (see step 5 below)
 The following steps detail the user authentication process:
 * The user selects Sign in in the website.
 * The browser redirects the user to the Azure Active Directory (Azure AD) sign in page.
 * The user signs in.
 * Azure AD redirects the user's session back to the web application. The URL includes an access token.
 * The web application calls an API and includes the access token in the authentication header. The application ID is sent as the audience ('aud') claim in the access token.

* The back-end API validates the access token.
